What is Virtualization?

- ▶ Multiple virtual machines on the same physical host
- ▶ Lowest layer is the hypervisor, which provides the illusion
- ▶ Built by OS people
- ▶ Historically, simple bridge

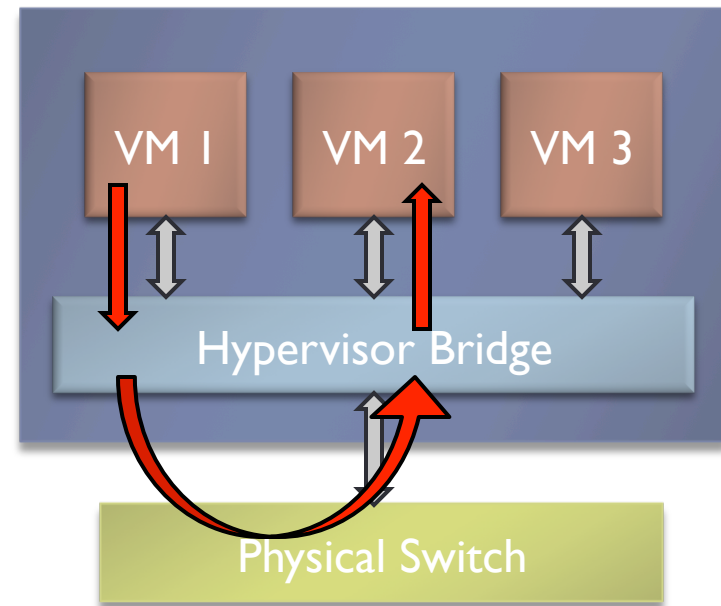

Impact of Virtualization on Networking

- ▶ **IP doesn't support mobility in a scalable manner**
 - ▶ Flat networks and VLANs don't scale
 - ▶ Policies don't follow host movement
- ▶ **Network infrastructure needs to change**
 - ▶ Know logical context (directly or tags)
 - ▶ Adapt to changes in the virtualization layer (signals or inference)

Hairpin Switching

- ▶ Use hardware that's already in the network
- ▶ Bridge already dumb, make it dumber (and simpler)
- ▶ All traffic bounces off the adjacent switch

Switching at the Edge

▶ Strengths

- ▶ Greater context
- ▶ Enforce policies early
- ▶ Inter-VM traffic has less overhead

▶ Weaknesses

- ▶ CPU overhead
- ▶ Additional switches to configure and monitor
- ▶ Historically, feature-weak

Advanced Edge Switches

- ▶ Hardware-offloading
- ▶ Centralized management
- ▶ Approaching feature-parity with hardware switches
 - ▶ Visibility
 - ▶ ACLs
 - ▶ Quality of Service
- ▶ Examples: VMware vSwitch, Cisco Nexus 1000V, Open vSwitch

Open vSwitch

- ▶ Visibility (NetFlow, sFlow, SPAN/RSPAN)
- ▶ Fine-grained ACLs and QoS policies
- ▶ Centralized control through OpenFlow
- ▶ Port bonding, GRE, and IPsec
- ▶ Works on Linux-based hypervisors: Xen, XenServer, KVM, VirtualBox
- ▶ In the process of being upstreamed to Linux
- ▶ Open source, commercial-friendly Apache 2 license
- ▶ Multiple ports to physical switches

Open vSwitch Contributors

Approaches Compared

- ▶ Cost
- ▶ Performance
- ▶ Tagging

Cost

- ▶ Hairpin switching may be able to use existing equipment, but becomes aggregation device that must scale to a much larger number of virtual interfaces
- ▶ Edge can support larger number of policy rules
- ▶ Edge switch is just software, which makes it easy to add new features
- ▶ Without hardware acceleration, both approaches consume hypervisor CPU cycles
- ▶ Edge can always fall-back to software when hardware not available

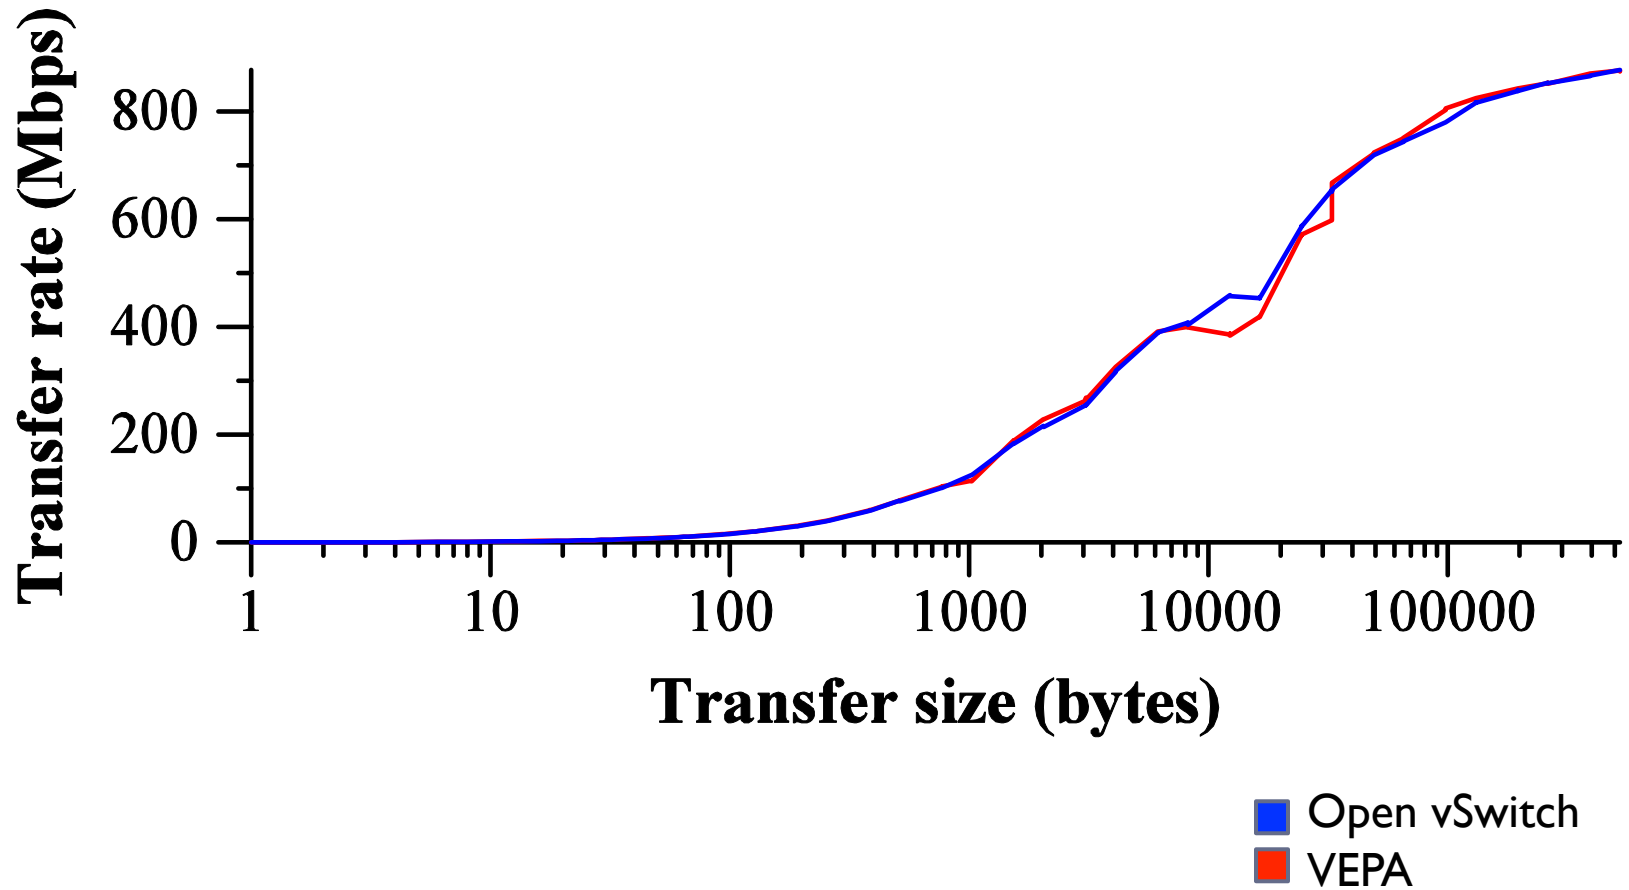

Performance

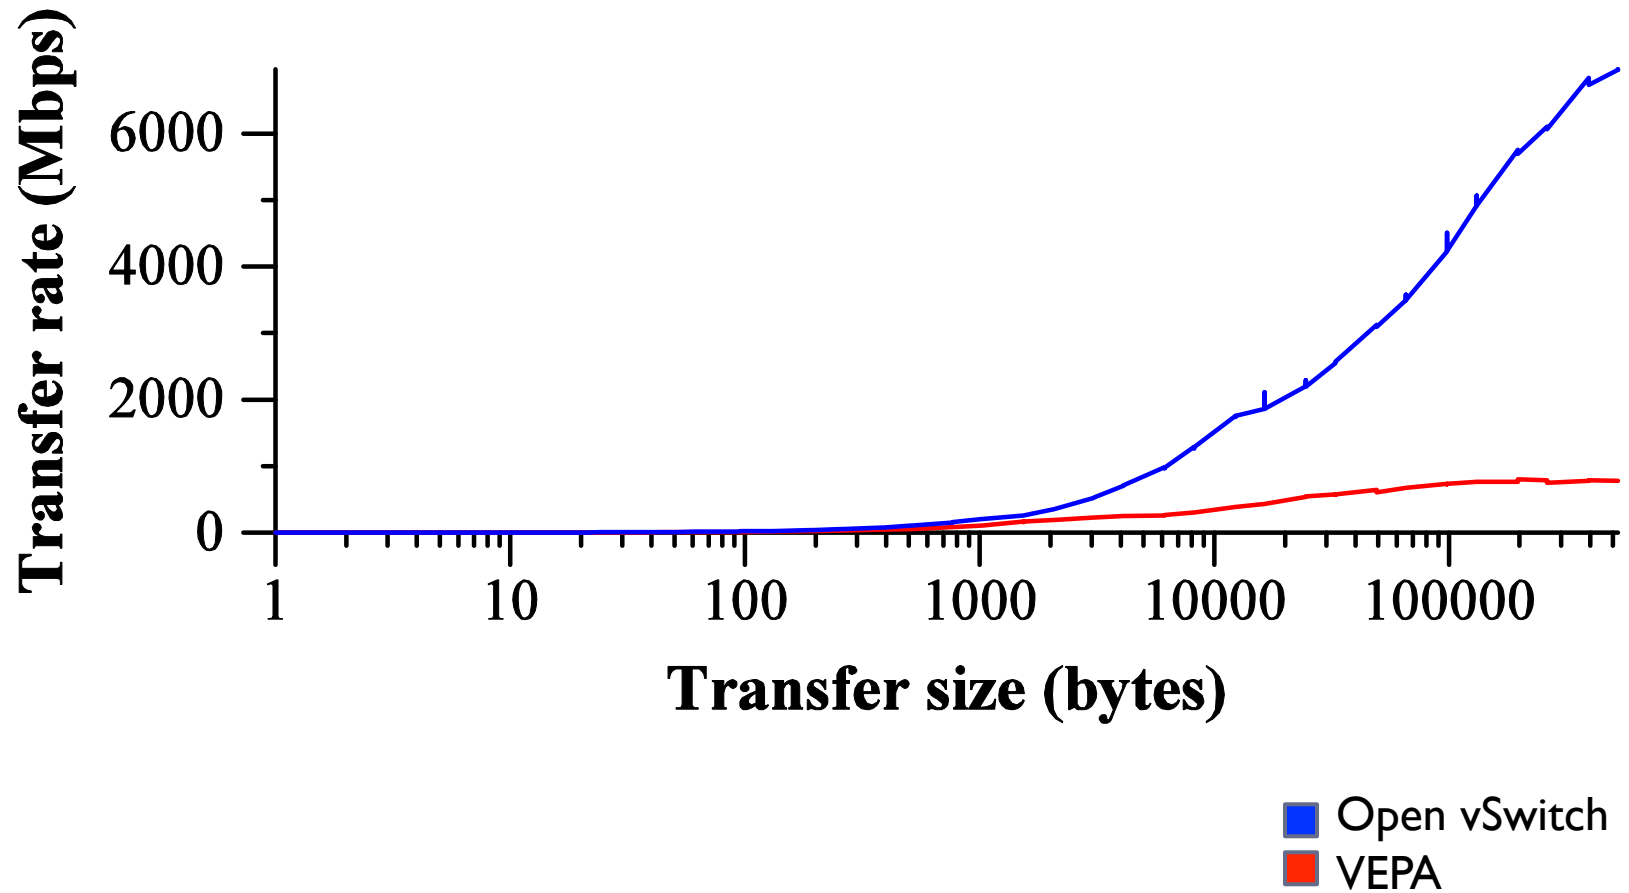

- ▶ Edge switches have been demonstrated at 40Gbps—at significant CPU overhead
- ▶ Traffic can be dropped closer to the source with edge switch—important in clouds with over-subscribed links and untrusted sources
- ▶ Both need offloading to not take CPU hit
- ▶ Checksum and TSO offloading provide big wins; SR-IOV even bigger
- ▶ Edge will be faster for local VM-to-VM traffic

Off-box Performance

On-box Performance

Tagging

- ▶ Without tags, hairpin switch must rely on fields that are easily spoofed
- ▶ Distinguish context, but don't say anything about the contexts—need port profiles
- ▶ Tag space limited and may cause issues with multicasting and mobility
- ▶ On the plus side, may provide context throughout the network

Future

- ▶ **NICs will do the heavy-lifting**
 - ▶ New types of offloading
 - ▶ Bypass the hypervisor in the common case (e.g., SR-IOV)
 - ▶ Push the datapath into the NIC
- ▶ **Edge is approaching feature-parity with high-end switches**
- ▶ **Physical switches adding same control interfaces as edge, for a unified control interface throughout the network**

Conclusion

- ▶ Hairpin switches attractive when applying similar policies over all nodes or in aggregate with little local VM-to-VM traffic
- ▶ Edge switches provide more flexibility and fine-grained control at cost of hypervisor CPU cycles
- ▶ Best approach likely uses both
- ▶ Need common standardized control interface
